1 Introduction

1.1 Scope

This document provides a complete description of the AMD Advanced Media Framework (AMF) Video Encoder Component. This component exposes the AMD Video Compression Engine, which provides hardware accelerated H.264 video encoding functionality.

Figure 1 provides a system overview of the AMF Video Encoder Component.

Figure 1 — System overview of the AMF Video Encode SDK

The AMF Video Encoder Component compresses RAW uncompressed video to an H.264 elementary bitstream.

The component does not provide a mechanism to handle audio compression, or stream multiplexing.

The component provides four different sets of pre-defined usages, which provide a convenient way for developers to configure the encoder to match the intended application use case. Advanced developers can also adjust encoding parameters to tailor the behavior to their specific application requirements.

1.2 Pre-defined Encoder Usages

The following table provides a brief overview of the encoding usage modes that have been defined:

Usage Mode	Intended use-cases	Comments
Transcoding	Transcoding, video editing	Favor compression efficiency and throughput over latency.
Ultra-low latency	Video game streaming	Optimize for extremely low latency use cases (e.g. cap the number of bits per frame), to enable high-interactivity applications.
Low Latency	Video collaboration, remote desktop	Optimize for low latency scenarios but allow occasional bitrate overshoots to preserve quality.
Webcam	Video conferencing	Optimize for a low-latency video conferencing scenario.
HQ	High quality mode	Optimize for best subjective video quality with possible loss of performance.
HQLL	High quality low latency mode	Optimize for good quality with low latency.

Table 1. Encoding usage modes

Note: User can override the default settings for these pre-defined usages in Table A-3. Default values of parameters.

2 AMF Video Encoder VCE-AVC Component

The AMF Video Encoder VCE-AVC component provides hardware accelerated AVC/SVC encoding using AMD's VCE.

To instantiate the AMF Video Encoder component, call the `AMFFactory::CreateComponent` method passing `AMFVideoEncoderVCE_AVC` or `AMFVideoEncoderVCE_SVC` component IDs defined in the `public/include/components/VideoEncoderVCE.h` header.

2.1 Input Submission and Output Retrieval

The AMF Video Encoder component accepts `AMFSurface` objects as input and produces `AMFBuffer` objects for output.

In the Transcoding mode the encoder needs to accept at least 3 input frames before any output is produced. In low latency modes output becomes available as soon as the first submitted frame is encoded.

2.2 Encode Parameters

Annex A provides the detailed description of encoding parameters (i.e., encoder properties) exposed by the Video Encoder VCE-AVC component for the following four usages:

- Transcoding mode,
- Ultra-low latency mode,
- Low Latency mode,
- Webcam mode,
- HQ mode, and
- HQLL mode.

All properties are accessed using the `AMFPropertyStorage` interface of the Encoder object.

2.2.1 Static Properties

Static properties (e.g., profile, level, usage) must be defined before the `Init()` function is called, and will apply until the end of the encoding session.

2.2.2 Dynamic Properties

All dynamic properties have default values. Several properties can be changed subsequently and these changes will be flushed to encoder only before the next `Submit()` call.

2.2.3 Frame Per-Submission Properties

Per submission properties are applied on a per frame basis. They can be set optionally to force a certain behavior (e.g., force frame type to IDR) by updating the properties of the `AMFSurface` object that is passed through the `AMFComponent::Submit()` call.

2.2.4 SVC Properties

Scalable Video Coding (SVC) is enabled by setting `AMF_VIDEO_ENCODER_NUM_TEMPORAL_ENHANCEMENT_LAYERS` to a value that is greater than 1. `AMF_VIDEO_ENCODER_NUM_TEMPORAL_ENHANCEMENT_LAYER` is a dynamic property and can be changed at any time during an encoding session. To ensure proper support on Radeon RX 5000 Series or newer GPUs and Ryzen 2000 U/H series or newer APUs, `AMF_VIDEO_ENCODER_MAX_NUM_TEMPORAL_LAYERS` needs to be set before initializing the encoder to a value that is not smaller than the number of temporal enhancement layers. As an example, the maximum number of temporal layers shall be set to 4 if the number of temporal enhancement layers will be changed from 3 to 4 in an encoding session. The maximum number of temporal layers supported by the encoder can be queried from the encoder capabilities before initializing the encoder.

To define SVC parameters per layer, the following format must be used:

```
TL<Temporal_Layer_Number>.QL<Quality_Layer_Number>.<Parameter_name>
```

As an example with two temporal layers, to configure "Target bitrate" for the base/first temporal layer and first quality layer, the following parameter should be used:

```
TL0.QL0.TargetBitrate
```

To configure "Target bitrate" for the second temporal layer and first quality layer, the following parameter should be used:

When setting per layer parameters, the equivalent non-SVC layer parameters should not be set for the encoder otherwise the per layer configuration will be overwritten.

Remark: quality layers are not supported on VCE 1.0. "QL0" must be used for quality layers.

2.2.5 ROI Feature

Region of importance (ROI) feature provides a way to specify the relative importance of the macroblocks in the video frame. Encoder will further adjust the bits allocation among code blocks based on the importance, on top of the base rate control decisions. More important blocks will be encoded with relatively better quality.

The ROI map can be attached to the input frame on a per frame basis. Currently, the ROI map can only use system memory. The ROI map includes the importance values of each macro block, ranging from 0 to 10, stored in 32bit unsigned format. Refer to SimpleROI sample application for further implementation details.

2.2.6 Encoder Statistics Feedback

If an application sets the `AMF_VIDEO_ENCODER_STATISTICS_FEEDBACK` flag on for an input picture, the encoder will feedback to the application statistics for this specific picture. After the encoding ends, the application can retrieve by name the specific statistic(s) it is interested in. The supported encoder statistics are listed in Table A-4. This feature is supported by Radeon RX 5000 Series or newer GPUs as well as Ryzen 2000 U/H series or newer APUs.

2.2.7 Picture Transfer Mode

If an application enables `AMF_VIDEO_ENCODER_PICTURE_TRANSFER_MODE` for a specific input picture, it can dump out the reconstructed picture after encoding and/or it can inject a picture to be used as the reference picture during the encoding. It is worth noting that reference picture injection is a feature that is intended for advanced algorithm testing and exploration. It needs to be used with care since the internal DPB in the current encoding session will be overridden by the injected reference picture(s). The reader can refer to `SimpleFrameInjection` sample application for further implementation details. This feature is supported by Radeon RX 5000 Series or newer GPUs as well as Ryzen 2000 U/H series or newer APUs.

2.2.8 LTR Properties

LTR (Long Term Reference) is to manually select a reference frame which can be far away to encode current frame. Normally, the encoder selects last frame as reference or a frame at lower layer in the SVC case.

In AV1, maximum of 16 reference frames are supported according to the spec. These 16 reference frames are shared by SVC and LTR.

To use LTR, you need to set these properties as Static Properties:

`AMF_VIDEO_ENCODER_MAX_LTR_FRAMES`, Max number of LTR frames.

`AMF_VIDEO_ENCODER_LTR_MODE` default = `AMF_VIDEO_ENCODER_LTR_MODE_RESET_UNUSED`; remove/keep unused LTRs (not specified in property `AMF_VIDEO_ENCODER_FORCE_LTR_REFERENCE_BITFIELD`)

The `LTR_MODE` has two options:

```
enum AMF_VIDEO_ENCODER_LTR_MODE_ENUM
{
    AMF_VIDEO_ENCODER_LTR_MODE_RESET_UNUSED    = 0,
    AMF_VIDEO_ENCODER_LTR_MODE_KEEP_UNUSED
};
```

Reset_unused: encoder will discard all other LTR frames stored once a LTR frame is used as reference.

Keep_unused: encoder will not change other LTR frames stored once any LTR frame is used as reference. When we enable auto LTR mode in PA, this mode will be automatically selected internally and `AMF_VIDEO_ENCODER_MAX_LTR_FRAMES` will be set to `4` no matter what users set. For details of “auto LTR mode”, please refer to `AMF_Video_PreAnalysis_API` document.

There are two Frame Per-Submission Properties need be set to use LTR:

`AMF_VIDEO_ENCODER_MARK_CURRENT_WITH_LTR_INDEX` , Mark current frame with LTR index. `-1` means don't save current frame into LTR slots. `0~N` means save current frame into a LTR slot with index of `0~N` . Here N should be `<= AMF_VIDEO_ENCODER_MAX_LTR_FRAMES-1` .

When we use SVC encoding, only next base frame can be stored as LTR frame (i.e. only temporal layer number = `0` frames are allowed to be saved into LTR slot.)

`AMF_VIDEO_ENCODER_FORCE_LTR_REFERENCE_BITFIELD` , force LTR bit-field. This is a bit-field mask that indicate which LTR slot can be used as reference for current frame. `0b1` means only slot 0 can be used as reference. `0b10` means only slot 1 can be used as reference. `0b100` means only slot 2 can be used as reference...

`0b0` means no LTR frame will be used as reference for current frame hence current frame will select short term reference frame (usually last frame) as reference.

When there are multiple bits are enabled, for example: `0b1111` (=decimal 15), that means LTR slots 0,1,2 and 3 are all allowed to be selected as reference. In this case, the closest LTR frame to current frame will be selected.

When we encode a key frame or switch frame, all save LTR slots will be cleared.

Referring to a LTR frame not exiting in LTR slot will generate an Intra only frame.

- We restrict all SVC layers to have the same Rate Control method. Some RC parameters are not enabled with SVC encoding (e.g. all parameters related to B-pictures).
- QVBR, HQVBR and HQCBR are only supported if PreAnalysis is enabled.
- QVBR, HQVBR and HQCBR target improving subjective quality with the possible loss of objective quality (PSNR or VMAF).

Default Value: `false`

Description: End of stream.

Name: `AMF_VIDEO_ENCODER_MARK_CURRENT_WITH_LTR_INDEX`

Values: -1 ... MaxOfLTRFrames -1

Default Value: N/A

Description: If != -1, the current picture is coded as a long-term reference with the given index.

Remarks:

- When the user controls N LTRs (using the corresponding Create parameter), then the LTR Index the user can assign to a reference picture varies from 0 to N-1. By default, the encoder will “use up” available LTR Indices (i.e. assign them to references) even if the user does not request them to be used.
- When LTR is used with SVC encoding, only base temporal layer pictures can be coded as LTR. In this case, the request to mark the current picture as LTR would be delayed to the next base temporal layer picture if the current picture is in an enhancement layer. If the user submits multiple requests to mark current as LTR between base temporal layer pictures, then only the last request is applied.

Name: AMF_VIDEO_ENCODER_FORCE_LTR_REFERENCE_BITFIELD

Values: Bitfield MaxOfLTRFrames (max possible 16 bits)

Default Value: 0

Description: Force LTR Reference allowed bitfield. If == 0, the current picture should predict from the default reference. If != 0, the current picture should predict from one of the LTRs allowed by the bitfield (bit# = LTR Index#).

Remarks:

- E.g. if Bit#0 = 1, then the existing LTR with LTR Index = 0 may be used for reference. The bitfield may allow more than one LTR for reference, in which case the encoder is free to choose which one to use. This bitfield also disallows existing LTRs not enabled by it from current/future reference.
- E.g. if Bit#1 = 0, and there is an existing reference with LTR Index = 1, then this LTR Index will not be used for reference until it is replaced with a newer reference with the same LTR Index.
